Abstract

Lorem ipsum.

Definition 1 (Family). A “ \mathcal{U} -family on type A ” is¹ simply a pair (I, f) where $I : \mathcal{U}$ and $f : I \rightarrow A$. We denote the type of \mathcal{U} -families by \mathbf{Fam} i.e. $\mathbf{Fam}_{\mathcal{U}}(A) \equiv \Sigma_{(I : \mathcal{U})} I \rightarrow A$.

Definition 2 (Directed family). A family (I, f) on some type A is called *directed* iff (1) I is inhabited, and (2) for every $i, j : I$, there exists some $k : I$ such that $f(k)$ is the upper bound of $\{f(i), f(j)\}$.

Our definition of a frame is parameterised by three universes: one for the carrier set, one for the order, and one for the index type of families on which the join operation is defined. We adopt the convention of using universe variables of \mathcal{U} , \mathcal{V} , and \mathcal{W} for these respectively.

Definition 3 (Frame). A $(\mathcal{U}, \mathcal{V}, \mathcal{W})$ -frame consists of:

- an h-set $|F| : \mathcal{U}$,
- a partial order $_ \leq _ : |F| \rightarrow \Omega_{\mathcal{V}}$,
- a top element $\top : |F|$,
- a meet operation i.e. an operation $_ \wedge _ : |F| \rightarrow |F| \rightarrow |F|$ such that $x \wedge y$ is the GLB of x and y for every $x, y : |F|$, and
- a join operation i.e. an operation $\bigvee _ : \mathbf{Fam}_{\mathcal{W}}(|F|) \rightarrow |F|$ such that given a family $\{x_i\}_{i \in I}$, $\bigvee_i x_i$ is the LUB of $\{x_i\}_{i \in I}$,

such that binary meets distribute over arbitrary joins:

$$x \wedge \bigvee_{i:I} y_i = \bigvee_{i:I} x \wedge y_i$$

for every $x : |F|$, family $\{y\} : \mathbf{Fam}_{\mathcal{W}}(|F|)$.

A nucleus on a frame F is an equivalent characterisation of a regular monomorphism on the locale corresponding to F .

Definition 4 (Nucleus). A nucleus on a $(\mathcal{U}, \mathcal{V}, \mathcal{W})$ -frame F is an endofunction $j : |F| \rightarrow |F|$ satisfying:

- (meet-preservation) $j(x \wedge y) = j(x) \wedge j(y)$;
- (inflation) $x \leq j(x)$; and
- (idempotence) $j(j(x)) \leq j(x)$.

for every $x, y : |F|$.

We write $\mathbf{Nucleus}(F)$ to denote the type of nuclei on a given frame F .

Proposition 1. Given any nucleus F , $\mathbf{Nucleus}(F)$ is an h-set.

Definition 5 (Scott-continuity). A function $f : |F| \rightarrow |G|$ from a $(\mathcal{U}, \mathcal{V}, \mathcal{W})$ -frame F to a $(\mathcal{U}, \mathcal{V}, \mathcal{W})$ -frame G is called *Scott-continuous* iff given any *directed* $\{x_i\} : \mathbf{Fam}_{\mathcal{W}}(|F|)$,

$$f \left(\bigvee_{i:I}^F x_i \right) = \bigvee_{i:I}^G f(x_i).$$

¹It would be reasonable to require I to be an h-set and f to be injective but we are providing a direct translation of the definition in our formalisation. This definition might have to be updated with these requirements.

0.1 Meet-semilattice of nuclei

Nuclei form a meet-semilattice when ordered pointwise.

Definition 6. The type of nuclei on a given frame F forms a meet-semilattice as follows:

- order: given nuclei j and k , $j \leq k \equiv \forall x \in |F|. j(x) \leq k(x)$;
- top nucleus: $_ \mapsto \top_F$; and
- meet of two nucleus: $j \wedge k \equiv x \mapsto j(x) \wedge_F k(x)$.

The fact that $j \wedge k$ satisfies the nucleus laws is given in Proposition ??.

Proposition 2. Given two nuclei j and k on some frame F , the function $x \mapsto j(x) \wedge k(x)$ is a nucleus.

Proof. Inflation is direct from the inflation of j and k and the fact that $j(x) \wedge k(x)$ is the GLB of $j(x)$ and $k(x)$. To see that meet-preservation holds, let $x, y : |F|$. We have:

$$\begin{aligned} j(x \wedge y) \wedge k(x \wedge y) &= j(x) \wedge j(y) \wedge k(x) \wedge k(y) \\ &= (j(x) \wedge k(x)) \wedge (j(y) \wedge k(y)). \end{aligned}$$

For idempotence, let $x : |F|$. We have:

$$\begin{aligned} j(j(x) \wedge k(x)) \wedge k(j(x) \wedge k(x)) &\leq j(j(x)) \wedge j(k(x)) \wedge k(j(x)) \wedge k(k(x)) \\ &\leq j(j(x)) \wedge k(k(x)) \\ &\leq j(x) \wedge k(x). \end{aligned}$$

□

The nontrivial part of the patch frame construction is the join of a family $\{k_i\}_{i:I}$. Defining it as

$$\bigvee_i k_i \quad \equiv \quad x \mapsto \bigvee_{i \in I} k_i(x)$$

does not work as it is not idempotent and hence not a nucleus. The construction I have formalised (due to Escardó [1]) is based on the idea that, if we start with a family $\{k_i\}_{i \in I}$ of nuclei, we can consider the family

$$\{k_{i_0} \circ \dots \circ k_{i_n}\}_{(i_0, \dots, i_n) : \text{List}(I)},$$

which will always be directed. However, this works only on Scott-continuous nuclei. Let us write this a bit more precisely as follows:

Definition 7. Let $K \equiv \{k_i\}_{i \in I}$ be a family of nuclei on a given $(\mathcal{U}, \mathcal{V}, \mathcal{W})$ -frame F . We define K^* as the family $(\text{List}(I), \mathfrak{d})$ where \mathfrak{d} is defined as:

$$\begin{aligned} \mathfrak{d}([\]) &\equiv \text{id}; \\ \mathfrak{d}(i :: is) &\equiv \mathfrak{d}(is) \circ k_i. \end{aligned}$$

We use the following proposition to construct the patch frame.

Proposition 3. Given a family K of Scott-continuous nuclei, K^* is always a directed family of Scott-continuous prenuclei (i.e. a prenucleus is an endofunction satisfying all nuclei laws except idempotence).

Definition 8 (Patch frame over a frame F). Let F be a $(\mathcal{U}, \mathcal{V}, \mathcal{W})$ -frame. We define the patch frame on F as follows:

- the underlying meet-semilattice is as given in Defn. 6;
- given a family $K \equiv \{k_i\}_{i \in I}$ of Scott-continuous nuclei, its join is defined as:

$$\bigvee K \quad \equiv \quad x \mapsto \{\alpha(x) \mid \alpha \in K^*\}.$$

The proof of the distributivity law is not straightforward and we omit it.
